

The background of the entire slide is a movie poster for 'Finding Nemo'. It features a deep blue ocean scene with sunlight filtering down from the top center. A large school of silver fish swims towards the viewer, while a smaller school of blue tangs swims away. In the center, a small orange and white clownfish (Nemo) is visible. The text 'There are 3.7 trillion fish in the ocean.* They're looking for one.' is in the lower left. The Disney Pixar logo and the title 'FINDING HERMAPHRODITES' are in the bottom left, with a wavy line underneath. The release date 'May 30' is in the bottom right.

There are 3.7 trillion fish in the ocean.*
They're looking for one.

“Inverse” morphological transformation

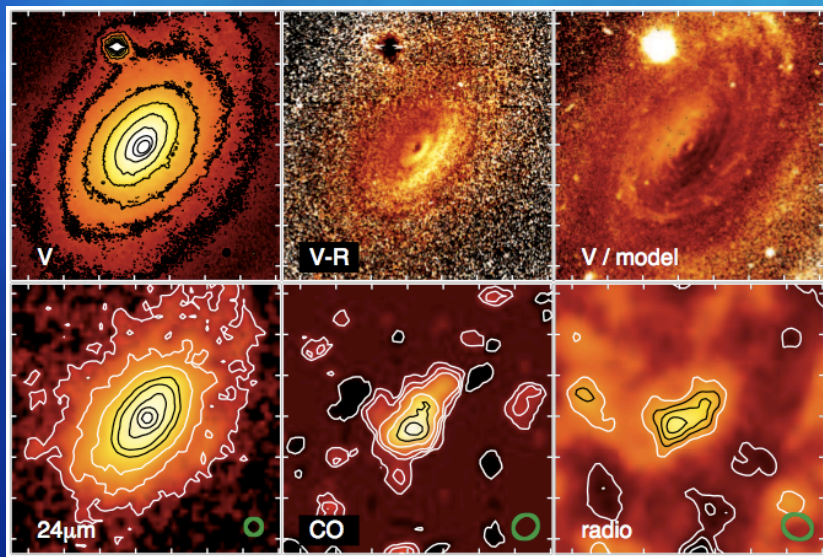

$t = 0.61 \text{ Gyr}, z = 7.01$

Kobayashi 2008

Low z examples

Martin Bureau's talk demonstrates the power of multi-wavelength studies.

NGC 807, Young et al 2008

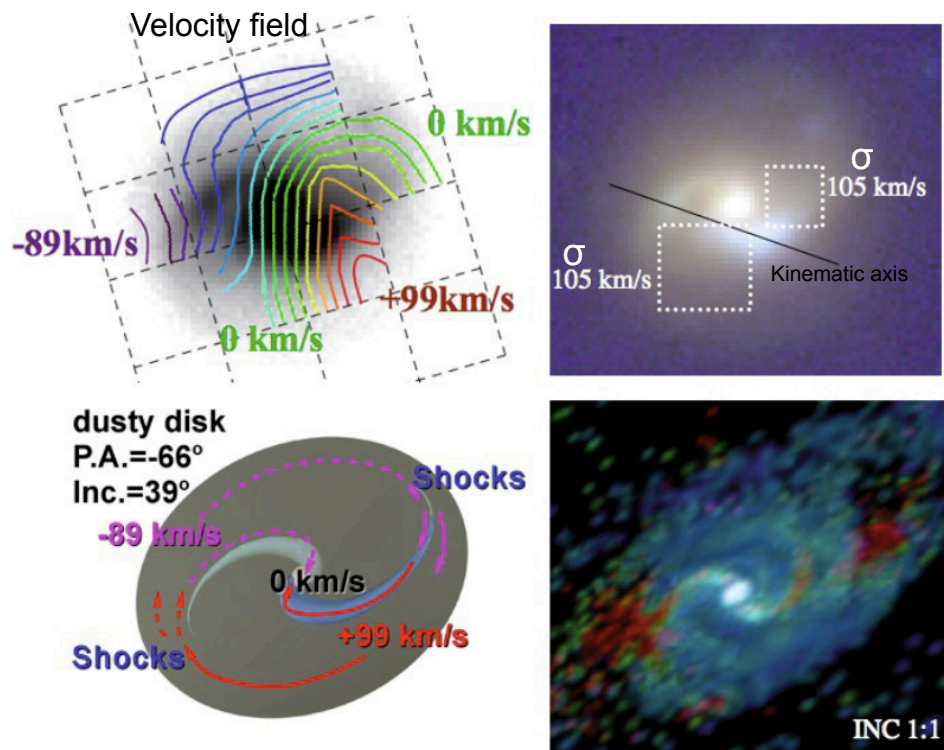

Young et al 2008: MIR & FIR emission in E/S0s with molecular gas

- $0.05 < \text{SFR} < 0.7 \text{ Mo/yr}$
- $1.5 < t_{\text{gas depletion}} < 7.7 \text{ Gyr}$
- $10^{10} < M_{\text{stellar}} < \text{few} \times 10^{11}$

=> final disk mass ~ few % of bulge at best.

Intermediate z example

If mergers occurred at $z \sim 1-2$, remnants may be visible at $z \sim 0.6$, but disks may be enshrouded by dust.

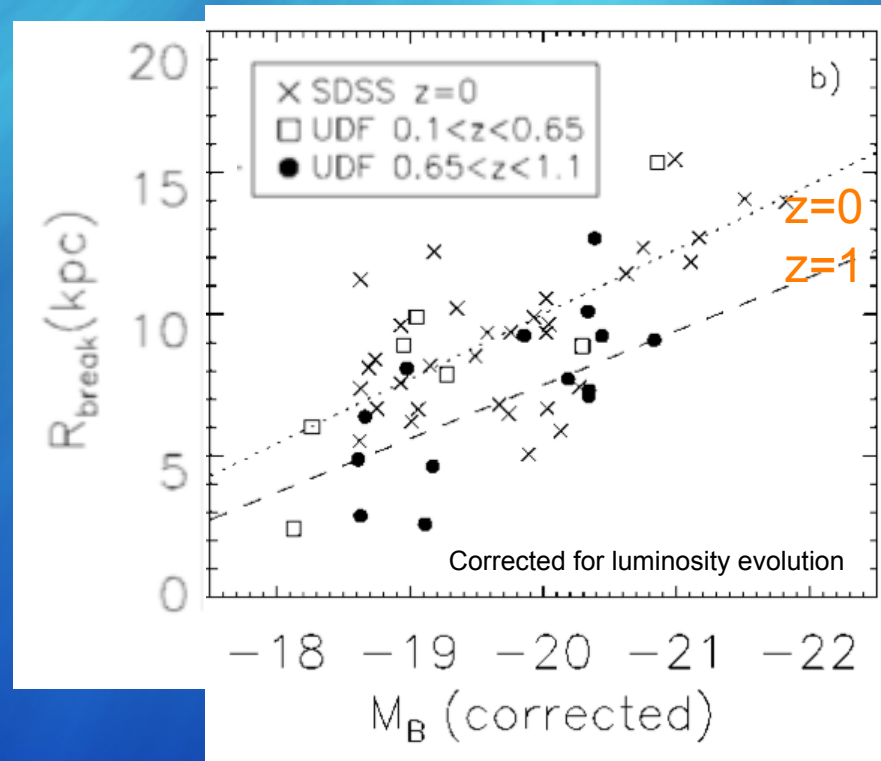

Simulation

- Hammer et al 2009:
J033245.11-274724.0 $z=0.43$, compact, LIRG, Mass \sim Milky Way.
- Blue bulge + red disk + bar system
- Disk contributes $\sim 81\%$ of M_{stellar} and $\sim 90\%$ of SFR.
- SFR ~ 20 Mo/yr, $M_{\text{gas}} \sim 2.3 \times 10^{10}$ Mo ($\sim 40\%$ total mass)
- Large fraction of young stars (< 0.3 Gyr: 20%, 0.5-0.8 Gyr: 30%)
- σ peaks at ends of arms

Galaxy may reach local Tully Fisher relationship if all gas consumed by $z \sim 0$

Evolution of disk size since $z=1$

- Trujillo & Pohlen (2005): **small to moderate (~25%) inside-out growth of the disk galaxies since $z \sim 1$**

High z example?

Smith et al 2002

ERO J003707+0909.5: $z = 1.6$ L^*
early-type galaxy.

$R-K = 5.4$

$D/B \sim 0.25$

Bulge passively evolving

Disk modestly star-forming

$SFR \sim 6 \text{ Mo/yr}$

Possess characteristics of both
ellipticals & spirals

⇒ Will turn into a spiral at $z=0$

Smith et al
called it
“Transvestite”

Hermaphrodite: an organism having both male and female reproductive organs. In many species, hermaphroditism is a common part of the life-cycle. (wikipedia)

Hermaphrodite galaxy

- an early type galaxy in the process of turning back into a spiral

Detailed Research on Androgynous Galaxies (DRAG)

Can we find nearby examples of hermaphrodites?

- Sample:
 - Nearby, HI rich dust-lane ellipticals (Oosterloo et al 2002, 2007)
- Observations:
 - Deep H α imaging with ESO NTT EMMI
 - Exposures ~10x deeper than SINNG.
 - Extinction correction from Driver et al (2007) empirical relation: $AR=0.41$ mag.

NGC 3108 Ha+R+HI

Red = H α
Green = R
Blue = 21cm

20 kpc

SFR = 0.42 Mo/yr
 $M_{\text{HI}} = 2.3 \times 10^9 \text{ Mo}$

IC5063 Ha+R+HI

Red = H α
Green = R
Blue = 21cm

14 kpc

SFR = 0.04 Mo/yr
 $M_{\text{HI}} = 3.9 \times 10^9 \text{ Mo}$

Luminosity Function of HII regions (HIILF)

HIILF of both gals have slope of -2.2

HIILFs qualitatively resemble those of late-type Local Group gals

- NGC 3108 comparable to M33 (Sc)
- IC 5063 comparable to NGC 6822 (Irr)

Lack very bright HII regions

- Unresolved -- upper limit ~ 150 pc (NGC 3108) – 310 pc (IC 5063)

Gas surface density

Gas surface densities:

- 4 Mo pc^{-2} (NGC 3108)
- 2.4 Mo pc^{-2} (IC 5063),

i.e. stars are forming at Kennicutt threshold or slightly below (beam size 4 kpc)

Summary of properties

	M_{stellar} (M_{\odot})	M_{HI} (M_{\odot})	SFR (M_{\odot}/yr)	D/B (10 Gyr)
NGC 3108	3.6×10^{11}	2.3×10^9	0.42	0.02
IC 5063	4.4×10^{11}	3.9×10^9	0.04	0.001

Will not transform to giant disk
systems without additional gas
and boost in SFR

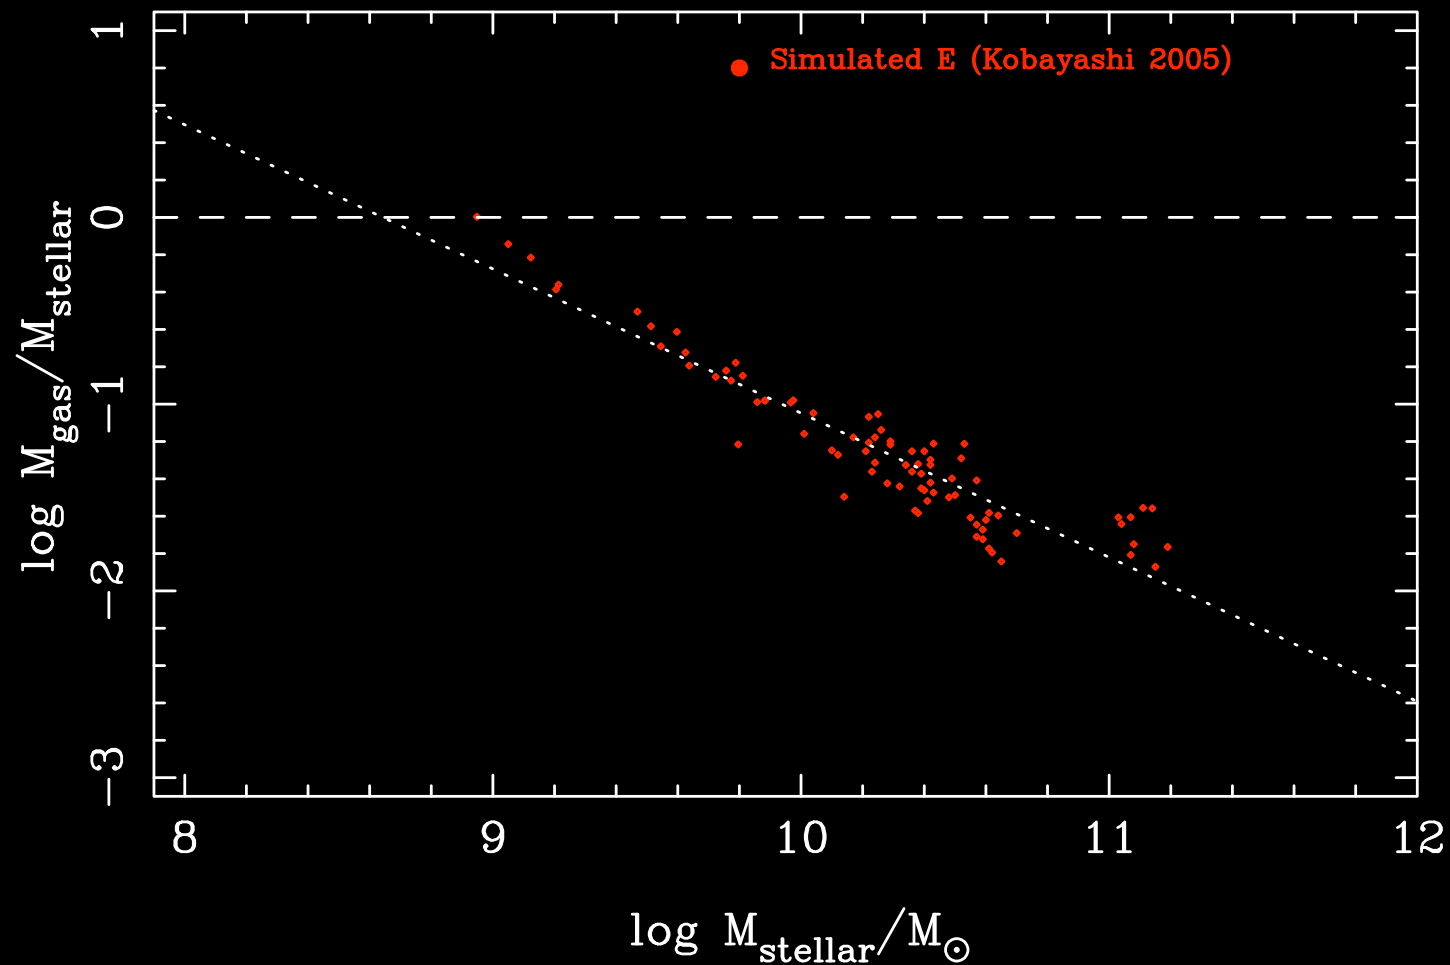

Where to find Present-day Hermaphrodites?

Predicting future Disk-to-bulge ratios

Two key questions:

- Is there enough gas to grow a new disk?
- Is the SFR high enough?

Gas content of field early type galaxies

Gas content of field early type galaxies

Gas content of field early type galaxies

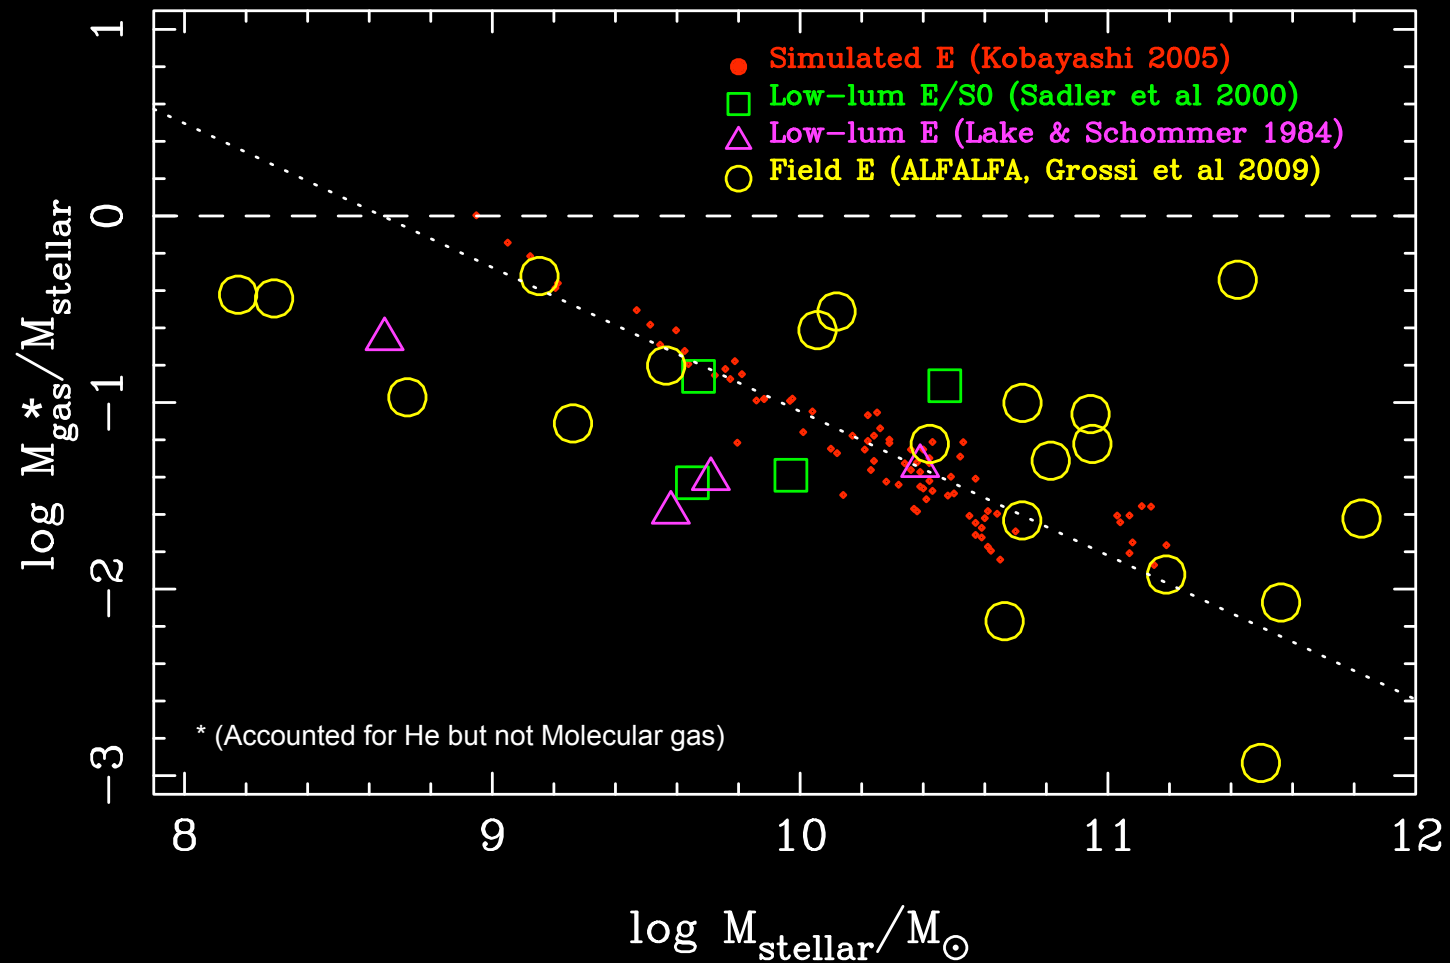

ALFALFA survey (Grossi et al 2009)

- Volume selected ($V < 3000$ km/s) from SDSS, visually identified Es in low density environments
- ~25% detection rate of these, 60% star forming (not AGN)

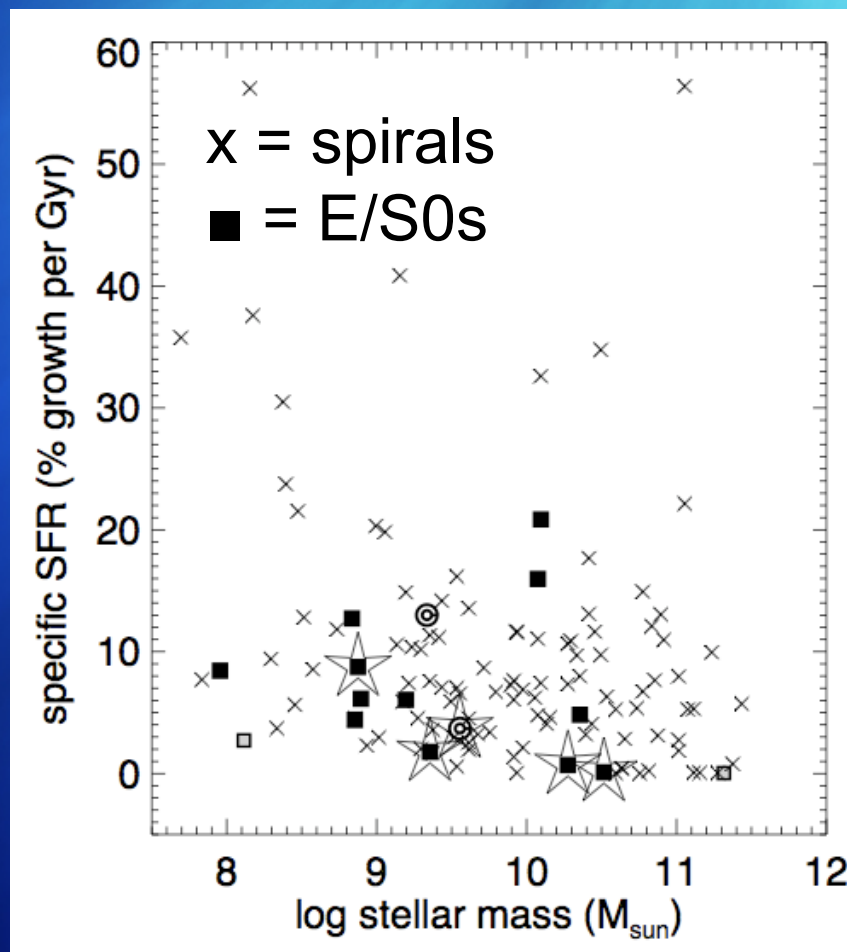

Blue colours -> Young stellar pop esp in low mass subsample.

Gas content of field early type galaxies

SFR of blue sequence E/S0s

Kannappan et al 2009:

- Blue-sequence E/S0s have specific SFR comparable to spirals (2-20% per Gyr).
- - significant disk growth within Hubble time
- Galaxy Zoo (Schawinski et al 2009): $0.5 < \text{SFR} < 50$ M_{sun}/yr

Conclusions

- Inverse morphological transformation is occurring even at low redshifts
- Present-day massive ($M_{\text{stellar}} \sim 10^{11}$) early-type galaxies will fail to turn into spirals -- disk mass after Hubble time at most a few % of bulge
- Low mass (10^8 – few 10^9 Mo) Early-type galaxies in low density regions may be good present-day hermaphrodite candidates, but they will not turn into substantial disk systems
